Linear Models with the rstanarm R Package

Ben Goodrich April 13, 2020

Difficulty of Analytical Bayesian Inference

· Bayes Rule for an unknown parameter (vector) $m{ heta}$ conditional on known data (vector) $m{y}$ can be written as

$$f\left(oldsymbol{ heta} \mid \mathbf{y}
ight) = rac{f\left(oldsymbol{ heta}
ight)f\left(\mathbf{y} \mid oldsymbol{ heta}
ight)}{f\left(\mathbf{y}
ight)} = rac{f\left(oldsymbol{ heta}
ight)f\left(\mathbf{y} \mid oldsymbol{ heta}
ight)f\left(\mathbf{y} \mid oldsymbol{ heta}
ight)}{\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\ldots\int_{-\infty}^{\infty}f\left(oldsymbol{ heta}
ight)f\left(\mathbf{y} \mid oldsymbol{ heta}
ight)d heta_{1}d heta_{2}\ldots d heta_{K}}$$

- To obtain the denominator of Bayes Rule, you would need to do an integral
- The Risch Algorithm tells you if an integral has an elementary form (rare)
- · In most cases, we can't write the denominator of Bayes Rule in a useful form
- But we can draw from a distribution whose PDF is characterized by the numerator of Bayes Rule without knowing the denominator

Four Ways to Execute Bayes Rule

- 1. Draw from the prior predictive distribution and keep realizations of the parameters iff the realization of the outcome matches the observed data
 - Very intuitive what is happening but is only possible with discrete outcomes and only feasible with few observations and parameters
- 2. Numerically integrate the numerator of Bayes Rule over the parameter(s)
 - Most similar to what we did in the discrete case but is only feasible when there are few parameters and can be inaccurate even with only one
- 3. Analytically integrate the numerator of Bayes Rule over the parameter(s)
 - Makes incremental Bayesian learning obvious but is only possible in simple models when the distribution of the outcome is in the exponential family
- 4. Use MCMC to sample from the posterior distribution
 - · Stan works for any posterior PDF that is differentiable w.r.t. the parameters

Comparing Stan to Ancient MCMC Samplers

- · Like M-H, only requires user to specify numerator of Bayes Rule
- · Like M-H but unlike Gibbs sampling, proposals are joint
- Unlike M-H but like Gibbs sampling, proposals always accepted
- · Unlike M-H but like Gibbs sampling, tuning of proposals is (often) not required
- · Unlike both M-H and Gibbs sampling, the effective sample size is typically 25% to 125% of the nominal number of draws from the posterior distribution because ρ_1 can be negative in $n_{eff}=\frac{S}{1+2\sum_{k=1}^{\infty}\rho_k}$
- Unlike both M-H and Gibbs sampling, Stan produces warning messages when things are not going swimmingly. Do not ignore these!
- Unlike BUGS, Stan does not permit discrete unknowns but even BUGS has difficulty drawing discrete unknowns with a sufficient amount of efficiency

Linear Model

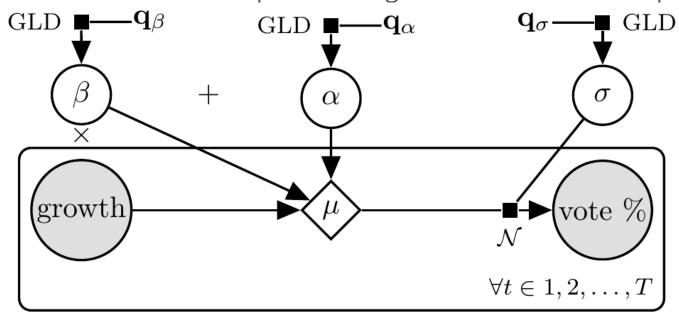

The prior predictive distribution for a linear model proceeds like

$$egin{aligned} &lpha \sim ????\ eta \sim ??? \end{aligned} \ orall n: \mu_n = lpha + \sum_{k=1}^K eta_k x_{nk} \ &\sigma \sim ??? \ &orall n: \epsilon_n \sim \mathcal{N}\left(0,\sigma
ight) \ &orall n: y_n = \mu_n + \epsilon_n \end{aligned}$$

where ??? indicates the parameter to the left is drawn from a distribution that is up to you.

Hibbs Bread Model for Presidential Vote %

What is the relationship between growth and incumbent party vote share?

Hibbs Model

Breakout Rooms

Use R to draw S=10000 times (using replicate) from the prior predictive distribution of the Hibbs model with reasonable GLD priors, which require

```
rstan::expose_stan_functions(file.path("..", "Week2", "quantile_functions.stan")) # GLD_icdf
source(file.path("..", "Week2", "GLD_helpers.R")) # GLD_solver and GLD_solver_bounded
ROOT <- "https://raw.githubusercontent.com/avehtari/ROS-Examples/master/"
hibbs <- readr::read_delim(paste0(ROOT, "ElectionsEconomy/data/hibbs.dat"), delim = " ")
hibbs$growth <- hibbs$growth - mean(hibbs$growth) # centering
y_ <- t(replicate(10000, {
    # fill in this part
}))</pre>
```

Answer: Hyperparameters of GLD Priors

```
a s alpha <- GLD solver bounded(bounds = c(0, 100), median = 52, IQR = 4)
## Warning in GLD solver bounded(bounds = c(0, 100), median = 52, IQR = 4): no asymmetry and
## steepness values achieve the bounds exactly; actual bounds are 0.00030366349862021 and
## 99.9989293029639
a s beta <- GLD solver(lower quartile = -2, median = 0, upper quartile = 3,
                       other quantile = 6.5, alpha = 0.9)
## Warning in GLD solver(lower quartile = -2, median = 0, upper quartile = 3, : solution
## implies a bounded lower tail at -3.50577775150403
a s sigma \leftarrow GLD solver(lower quartile = 2.5, median = 4, upper quartile = 6,
                        other quantile = 0, alpha = 0)
```

Answer: Prior Predictive Distribution

Checking the Prior Predictive Distribution

summary(vote_) # a little too wide

[1] 0.62395

In other words, for THESE 17 values of x, we EXPECT (over Y) to reject the false null hypothesis that $\beta=0$ in favor of the alternative hypothesis that $\beta>0$ at the 5% level with probability 0.624 when the true value of β is $\frac{1}{2}$.

- · What good is this PRE-DATA (on y_1, y_2, \ldots, y_{17}) statement?
- But in this case the posterior distribution is the same as the estimated sampling distribution of the OLS estimator across datasets

Breakout Rooms: IQ of Three Year Olds

- All examples from the reading (plus more) are available at https://github.com/avehtari/RAOS-Examples
- · At 36 months, kids were given an IQ test
- Suppose the conditional expectation is a linear function of whether its mother graduated high school and the IQ of the mother
- · In breakout rooms, draw from the prior predictive distribution of the outcome using independent normal priors on the intercept and coefficients and an exponential prior on σ

Utility Function for Predictions of Future Data

- For Bayesians, the log predictive PDF is the most appropriate utility function
- Choose the model that maximizes the expectation of this over FUTURE data

$$egin{aligned} \operatorname{ELPD} &= \mathbb{E}_Y \ln f\left(y_{N+1}, y_{N+2}, \ldots, y_{2N} \mid y_1, y_2, \ldots, y_N
ight) = \ \ln \int_{-\infty}^{\infty} \cdots \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} f\left(y_{N+1}, y_{N+2}, \ldots, y_{2N} \mid \mathbf{y}
ight) dy_{N+1} dy_{N+2} \ldots dy_{2N} pprox \ \sum_{n=1}^{N} \ln f\left(y_n \mid \mathbf{y}_{-n}
ight) = \sum_{n=1}^{N} \ln \int_{\Theta} f\left(y_n \mid oldsymbol{ heta}
ight) f\left(oldsymbol{ heta} \mid \mathbf{y}_{-n}
ight) d heta_1 d heta_2 \ldots d heta_K \end{aligned}$$

- · $f(y_n \mid \boldsymbol{\theta})$ is just the n-th likelihood contribution, but can we somehow obtain $f(\boldsymbol{\theta} \mid \mathbf{y}_{-n})$ from $f(\boldsymbol{\theta} \mid \mathbf{y})$?
- · Yes, assuming y_n does not have an outsized influence on the posterior

Pareto Smoothed Importance Sampling

Let
$$r_n^s=rac{1}{fig(y_n|\widehat{m{ heta}}^sig)}\proptorac{fig(\widehat{m{ heta}^s}|\mathbf{y}_{-n}ig)}{fig(\widehat{m{ heta}^s}|\mathbf{y}ig)}$$
 be the s -th importance ratio for y_n

· Fit a generalized Pareto model to these importance ratios, which have PDF

$$f\left(r_{n}\mid\mu,\sigma,k
ight)=rac{1}{\sigma}igg(1+rac{k\left(\mu-r_{n}
ight)}{\sigma}igg)^{-1-rac{1}{k}}$$

- In the 20% right tail, use an interpolated \hat{r}_n^s rather than r_n^s
- Doing so stabilizes the variances as long as the estimated shape parameters of the generalized Pareto distribution are not too large
 - $\hat{k}_n < 0.5$ is good and $\hat{k}_n \in [0.5, 0.7]$ is okay
 - $\hat{k}_n > 0.7$ is bad and $\hat{k}_n > 1.0$ is very bad

```

• What do you think is the prior \mathbb{R}^2 for a model of log(price)?

Do This Once on Each Computer You Use

- R comes with a terrible default coding for ordered factors in regressions known as "Helmert" contrasts
- Execute this once to change them to "treatment" contrasts, which is the conventional coding in the social sciences with dummy variables relative to a baseline category

```
cat('options(contrasts = c(unordered = "contr.treatment", ordered = "contr.treatment"))',
    file = "~/.Rprofile", sep = "\n", append = TRUE)
```

- Without this, you will get a weird rotation of the coefficients on the cut and clarity dummy variables
- "contr.sum" is another reasonable (but rare) choice

The stan_lm Function

```
post <- stan lm(log(price) \sim carat * (log(x) + log(y) + log(z)) + cut + color + clarity,
                data = diamonds, prior = R2(location = 0.8, what = "mode"), adapt delta = 0.9)
                                                           $ colorI
                                                                                 -0.37 -0.38 -0.37 -0.38 ...
                                                                           : num
